Homework 2 of Computational Mathematics

AM15 黃琦翔 111652028

March 27, 2024

1. $x^3 = x + 1 \implies x^2 = 1 + \dfrac{1}{x} \implies x = \sqrt{1 + \dfrac{1}{x}} = g(x)$. $p_1 = g(p_0) = \sqrt{1+1} = \sqrt{2} \approx 1.414$. $p_2 = g(p_1) = \sqrt{1 + \dfrac{1}{\sqrt{2}}} \approx 1.3065$. $p_3 = g(p_2) \approx 1.3172$. $p_4 = g(p_3) \approx 1.326$. $p_5 = g(p_4) \approx 1.324$ Then, p_4 is the answer that we want to find.

2. Let $f(x) = x^3 + x - 4$, $f'(x) = 3x^2 + 1 < 49$ for all $x \in [1,4]$. Thus, for $|x - y| < \dfrac{10^{-3}}{49} \approx 2.0409e - 5$, $|f(x) - f(y)| < 10^3$. Find n s.t. $3 \cdot 2^{-n} < 2.0409e - 5$, $n > -\log_2(\dfrac{2.0409e - 5}{3}) \approx 17.1653$. Thus, the bound of the number of iteration is 18. Then, by python code below, the root is about 1.3787.

```
HW2 > ◆ HW2.py > ...
1    a = [1]
2    b = [4]
3
4    def f(x):
5        return x**3 + x - 4
6
7    while 1:
8        mid = (a[-1] + b[-1])/2
9        val = f(mid)
10       print(mid, val)
11
12       if abs(val) < 0.0001:
13           break
14       elif val > 0:
15           b.append(mid)
16       else:
17           a.append(mid)
```

```

3. In this question, we let $p_{n+1} = g(p_n)$ and $p = \sqrt[3]{21}$. And by $\lim\limits_{n\to\infty} \dfrac{|p_{n+1} - p|}{|p_n - p|^\alpha} = \lambda$,

$$\dfrac{|p_{n+1} - p|}{|p_n - p|} \approx \dfrac{\lambda |p_n - p|^\alpha}{\lambda |p_{n-1} - p|^\alpha} \approx \left| \dfrac{p_n - p}{p_{n-1} - p} \right|^\alpha, \text{ then } \alpha \approx \dfrac{\ln |(p_{n+1} - p)/(p_n - p)|}{\ln |(p_n - p)/(p_{n-1} - p)|}.$$

Then, by observing the function, we get b is quadratic convergence (Newton's method). In the meanwhile, though $\sqrt[3]{21}$ is a fixed point of c, but it will diverges or converges to 0 for any open interval contains $\sqrt[3]{21}$.

Thus, by result of iteration with python below, the order of speed of convergence is b > d > a.

```python
20
21  v def problem_3():
22        import math
23        p = 21**(1.0/3)
24  v     def a(x):
25            return (20*(x**3)+21)/(21*(x**2))
26
27  v     def b(x):
28            return x- (x**3 - 21)/(3*(x**2))
29
30  v     def c(x):
31            return x - (x**4 - 21*x)/(x**2 - 21)
32
33  v     def d(x):
34            return math.sqrt(21/x)
35
36  v     def Alpha(f, x):
37            return math.log(abs((f(x) - p)/(x - p)))
38
39        functions = {"a": a, "b": b, "c":c, "d": d}
40
41  v     for i in functions.keys():
42            f = functions[i]
43            p_now = 1
44  v         for k in range(20):
45                p_now = f(p_now)
46                # print(k+1, "err:", abs(p_now - p))
47  v         try:
48                alpha = Alpha(f, f(p_now))/Alpha(f, p_now)
49                print(i, alpha)
50  v         except:
51                print(i, "Cannot compute alpha by this method.")
52
53            print("---")
54
55  v def problem_4():
56  v     def a(x):

4. $|g'(x)| = |-2^{-x}\ln(2)|$ is continuous and decreasing on $\mathbb{R}$. Thus, $g'(\frac{1}{3}) \approx 0.55015$. And since $g(\frac{1}{3}) \approx 0.79370 > \frac{1}{3}$ and $g(1) = \frac{1}{2} < 1$. By Theorem 2.3, $g(x)$ has unique fixed point on $[\frac{1}{3}, 1]$.

```
55 v def problem_4():
56 v     def g(x):
57             return 2**(-x)
58
59         x = 0.3334
60         step = 0
61 v     while abs(x-g(x)) >= 10**(-4):
62             x = g(x)
63             step += 1
64             print("step:", step, ",value:", x)
65
66         |
67 v if __name__ == "__main__":
68         problem_4()
```

By the result from python above, we need 12 steps to let error less than 10^{-4}. Since $|g'(x)| \leq \ln(2)2^{-x} \leq$ 0.551, we take $k = 0.551$ and $p_0 = 1$. $|p_n - p| \leq \dfrac{k^n}{1-k}|p_1 - p| \approx k^n \cdot 1.113585746 \leq 10^{-4}$. Then, $n \geq 15.633566$, that is, the bound is 16 times of iteration.

5. (a) Let x_* be nonzero fixed point of g, $x_* = 2x_* - Ax_*^2 \implies x_* = Ax_*^2 \implies x^*A = 1$. Thus, $x_* = \dfrac{1}{A}$.

(b) Since $g'(x) = 2 - 2Ax$ and we need $|g'(x)| < k < 1$,

$$|2 - 2Ax| < k \iff -k < 2 - 2Ax < k$$
$$\iff \frac{k-2}{2A} < x < \frac{k+2}{2A}$$
$$\overset{k=1-\varepsilon}{\iff} \frac{1}{2A} + \frac{\varepsilon}{2A} < x < \frac{3}{2A} - \frac{\varepsilon}{2A}$$

Thus, $x \in \left(\dfrac{1}{2A} + \dfrac{3}{2A} \right)$.

6. Let $g(x) = \dfrac{x}{2} + \dfrac{A}{2x}$, and $g'(x) = \dfrac{1}{2} - \dfrac{A}{2x^2}$. For $x \in (\sqrt{A}, \infty)$, $|g'(x)| \leq \dfrac{1}{2}$. And since $x > \sqrt{A}$, $\dfrac{x}{2} + \dfrac{A}{2x} - \sqrt{A} = \dfrac{x^2 + A - 2Ax}{2x} = \dfrac{(x - \sqrt{A})^2}{2x} > 0$. Thus, if $x > \sqrt{A}$, $g(x) > \sqrt{A}$. By Corollary 2.5, $g(x)$ converges to $\sqrt{A}$ for all $(\sqrt{A}, \infty)$.

Then, for $x \in (0, \sqrt{A})$, $\dfrac{x}{2} + \dfrac{A}{2x} - \sqrt{A} = \dfrac{(A - x)^2}{2x} > 0$. Thus, for $0 < x < \sqrt{A}$, $g(x) > \sqrt{A}$, and then by the argument above, it will converge to $\sqrt{A}$, too.

Therefore, for $x_0 > 0$, x_n will converge to $\sqrt{A}$.

7. (a) $p_2 = p_1 - \dfrac{f(p_1)[p_0 - p_1]}{f(p_0) - f(p_1)} = -\dfrac{-1}{-1 + \cos(-1) - 1} = \dfrac{1}{-2 + \cos(1)} \approx -0.6850733573260451.$

$p_3 = p_2 - \dfrac{f(p_2)[p_1 - p_2]}{f(p_1) - f(p_2)} \approx -1.252076488909229.$

(b) $p_2 = p_1 - f(p_1) \cdot \dfrac{p_0 - p_1}{f(p_0) - f(p_1)} \approx -0.6850733573260451.$ Since $f(p_2) < 0$, $f(p_2) \cdot f(p_0) < 0$.

Then, $p_3 = p_2 - f(p_2) \cdot \dfrac{p_0 - p_2}{f(p_0) - f(p_2)} \approx -0.8413551256656522.$

8. From the question, we can rewrite it as $f(i) = 1000(1 - (1 + i)^{-30 \cdot 12}) - 135,000i = 0$. After testing, we know that $f(0.002) > 0$ and $f(0.01) < 0$.

```python
92
93   def problem_8():
94       def secant_method(f, x_1, x_2):
95           return x_1 - (f(x_1)*(x_2 - x_1))/(f(x_2) - f(x_1))
96
97       f = lambda x: 1000*(1-(1+x)**(-360))-135000*x
98       x = [0.002, 0.01]
99       for _ in range(8):
100          p = secant_method(f, x[-1], x[-2])
101          print(p, f(p))
102          x.append(p)
103
104  if __name__ == "__main__":
105      problem_8()
```

```

```

Then, by secant method and python, $i \approx 0.0067499171590712035$. Thus, the interest rate the borrower can afford is about $0.0067499171590712035 \cdot 12 = 0.080999005908854442 = 8.0999005908854442\%.$

9. (a) $\lim\limits_{n \to \infty} \dfrac{|1/(n+1)^k|}{|1/n^k|} = \lim\limits_{n \to \infty} \left(\dfrac{n}{n+1}\right)^k = 1$ for all k. Thus, p_n converges linearly.

(b) $\lim\limits_{n \to \infty} \dfrac{10^{-2^{n+1}}}{|10^{-2^n}|^2} = \lim\limits_{n \to \infty} 10^{-2^{n+1} + 2^n \cdot 2} = 1$. Thus, p_n converges linearly.
